

BUMPER FOR AN UMBRELLA

BACKGROUND OF THE INVENTION

1. Field of the Invention

The invention relates to a bumper for an umbrella, and particularly a bumper secured on a shank of the umbrella to provide a shock-absorbing ~~efficiency-effect~~ when the umbrella opens.

2. Description of Related Art

With reference to Fig. 4, a conventional umbrella is composed of a frame (50) and a canopy (60) mounted on the frame (50).

The frame (50) has a shank (52) with a top end, a sliding ring (54), a spreader (542), a stretcher (56), a rib set (58) and a ferrule (522). The sliding ring (54) is movably mounted on the shank (52) and has an enlarged round top (not numbered), a telescoping tube (not numbered) extending from the round top and a stretcher base (544) mounted on the telescoping tube. The spreader (542) is composed of multiple rods (not numbered) pivotally and radially formed around the enlarged round top of the sliding ring (54). The stretcher (56) is also composed of multiple rods (not numbered) pivotally and radially attached around the stretcher base (544). The rib set (58) is composed of multiple rods pivotally and radially attached at the top end of the shank (52) to support the canopy (60). Each rod of the stretcher (56) movably (what is moveably) connects one corresponding rod of the spreader (542) at a middle portion of the spreader rod and further has a distal end to pivotally connect to one corresponding rod of the rib set (58). Additionally, multiple retractable tabs (not shown) are formed on the shank (52) to selectively locate the sliding ring (54) at an extending position or at a retracting position.

Moreover, a limiting tube (70) is mounted on the shank (52) and secured under the top end of the shank (52) to selectively abut the stretcher base (544) of the sliding ring (54). Whereby, the limiting tube (70) enables the sliding ring (54) to stop in a preferred position to fully extend the stretcher (56) and keep the umbrella open.

However, the limiting tube (70) is usually made of rigid plastic and easily broken when the sliding ring (54) bumps against the limiting tube (70) whereby the umbrella malfunctions and must be thrown away. This is especially so when the umbrella is automatically extended by

means of securing a restituting spring (not shown) around the telescoping tube of the sliding ring (54). The restituting spring is compressed and the telescoping tube retracts into the sliding ring (54) when the umbrella is at the retracting position. When the tab locating the sliding ring (54) retracts, the sliding ring (54) is released and rapidly bumps the limiting tube (70), causing vibrations and damage to joints of the frame (10).

With reference to Fig. 5, to avoid the vibrations and damage caused by bumping, a spring (80) is mounted on the shank (52) between the top end of the shank (52) and the stretcher base (544) of the sliding ring (54). Although the spring (80) provides a shock absorbing efficiency effect to the umbrella, it is difficult to secure the spring (80) under the top end of the shank (52) whereby the spring (80) slides along the shank (52) when the sliding ring (54) does not abut against the spring (80). However, the spring (80) sliding on the shank (52) is easily trapped by the multiple tabs emerging out from the shank (52) such that the operation of the umbrella blocked and inconvenient.

The present invention has arisen to provide a bumper for an umbrella to overcome and obviate the drawbacks of the conventional umbrellas.

SUMMARY OF THE INVENTION

A first objective of the present invention is to provide a bumper for an umbrella that has an excellent shock-absorbing efficiency effect.

Further benefits and advantages of the present invention will become apparent after a careful reading of the detailed description in accordance with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a perspective view of a bumper in accordance with the present invention, wherein the bumper is secured on a frame of an umbrella;

Fig. 2 is an enlarged perspective view of the bumper in Fig. 1;

Fig. 3 is a partially enlarged cross-sectional side plane view of the bumper showing the shock-absorbing situation of the bumper;

Fig. 4 is a perspective view of a first embodiment of an umbrella in accordance with the prior art; and

Fig. 5 is a perspective view of a second embodiment of an umbrella in accordance with the prior art.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

With reference to Fig. 1, a bumper (30) for an umbrella composed of a frame (10) and a canopy (20), which is adapted to secure on the frame (10) of the umbrella.

The frame (10) has a shank (12) with a top end, a sliding ring (14), a spreader (142), a stretcher (16), a rib set (18) and a ferrule (122). The sliding ring (14) is movably mounted on the shank (12) and has an enlarged round top (not numbered), a telescoping tube (not numbered) extending from the round top and a stretcher base (144) mounted on the telescoping tube. The spreader (142) is composed of multiple rods (not numbered) pivotally and radially formed around the enlarged round top of the sliding ring (14). The stretcher (16) is also composed of multiple rods (not numbered) pivotally and radially attached around the stretcher base (144). The rib set (18) is composed of multiple rods pivotally and radially attached at the top end of the shank (12) to support the canopy (20). Each rod of the stretcher (16) pivotally connects one corresponding rod of the spreader (142) at a middle portion and further has a distal end to pivotally connect to one corresponding rod of the rib set (18).

With reference to Fig. 2, the bumper (30) is made of resilient material and shaped in a serpentine configuration. In Fig. 2, the bumper (30) is an undulating tube composed of a securing end (32), a serpentine middle portion (34), an abutting end (36) and a straight through hole (not numbered) defined through securing end (32), the serpentine middle portion (34) and the abutting end (36). The securing end (32) is adapted to secure under the top end of the shank (12) and further has a narrow distal edge to clamp on the shank (12). Multiple slits (322) are defined in the narrow distal edge to allow the narrow distal edge slightly ~~expanding~~ expand when the bumper (30) ~~secures~~ is secured under the top end of the shank (12). By clamping at the narrow distal end, the bumper (30) is securely attached under the top end of the shank (12) in position. The serpentine middle portion (34) is in the form of an undulating bar to make the bumper (30) have restitution spaces between two undulations. The abutting end (36) is adapted to abut on the stretcher base (144) and is shaped as a cubic block.

With reference to Fig. 3, when the sliding ring (14) bumps the abutting end (36) of the bumper (30), the serpentine middle section (34) is slightly compressed to damp the shock.

Therefore, the vibration and the damage to the frame (10) of the umbrella can be minimized to a non-damaging magnitude.

According to the above description, the bumper (30) is securely mounted under the top end of the shank (12) to avoid the bumper (30) sliding on the shank (12) and trapped by the tabs. Additionally, the bumper (30) is enabled to be compressed at the serpentine middle portion (34) to damp the shock caused by bumping of the sliding ring (32). Therefore, malfunction and damage to the umbrella are avoided.

Although the invention has been explained in relation to its preferred embodiment, many other possible modifications and variations can be made without departing from the spirit and scope of the invention as hereinafter claimed.
